Field of the Invention The present invention relates to a polycrystalline silicon thin film formed on a substrate made of glass, quartz, ceramics, metal, etc., and an application thereof. 2. Description of the Related Art A thin film transistor (hereinafter referred to as a TFT) formed on a glass substrate is widely used as a switching element or the like for a liquid crystal display. Especially, in an active matrix liquid crystal display, TFTs are formed in pixels, and in recent years, since high definition of the display is realized by forming the TFTs in pixels of sub-pixels at a higher density, there is a strong demand for further higher reliability. As an organic semiconductor material used for a semiconductor layer of the TFT, for example, polycrystalline silicon is used because it has a high mobility, and by using it, a high definition image can be obtained. However,

in order to form a polycrystalline silicon thin film on a glass substrate, it is necessary to use a high-temperature heat treatment of 1000° C. or more. Therefore, it is known that a thin film made of polycrystalline silicon has a defect in its crystal structure (in particular, a defect in grain boundaries) and is low in its reliability (for example, see Patent Reference 1). Further, in order to improve electrical characteristics of a TFT, for example, it is known that a TFT is formed by using a semiconductor thin film made of amorphous 82157476af
